

```
typewriter-mimicker
=====
```

Plain text to typewriter-style PDF.

The project has two deliberately separate stages.

- formatter

Haskell. Parses plain text conventions, wraps prose, preserves preformatted blocks, paginates a fixed-width page, and emits a deterministic glyph JSON model.

- renderer

Python. Reads the glyph model, rasterizes each glyph with light typewriter jitter and ink variation, adds a paper background, and writes a raster PDF. It also adds subtle line-level vertical drift to mimic small carriage return and paper advance variation.

The default renderer font is the bundled Special Elite typewriter face. It is licensed under the Apache License 2.0. See:

```
assets/fonts/SpecialElite-Apache-2.0.txt
```

Usage

Enter the development shell:

```
nix develop
```

Render in one command:

```
nix run . -- examples/sample.txt .artifacts/sample.pdf
```

Render with optional aged paper:

```
nix run . -- examples/sample.txt .artifacts/sample.pdf --paper aged
```

Generate glyph JSON:

```
mkdir -p .artifacts
stack --stack-yaml formatter/stack.yaml run -- examples/sample.txt \
  > .artifacts/pages.json
```

Render a PDF:

```
uv --project renderer run python renderer/main.py \
  .artifacts/pages.json \
  --output .artifacts/sample.pdf \
  --dpi 150
```

Run checks:

```
stack --stack-yaml formatter/stack.yaml test
```

```
uv --project renderer run pytest
```
